- Single Sideband (SSB)

Common Viva Questions on Analog Communication with Answers

Below is a compilation of frequently asked viva questions along with detailed answers to help prepare for exams.

1. What is Modulation? Why is it used in communication systems?

Answer: Modulation is the process of varying a carrier signal's parameters (amplitude, frequency, or phase) in accordance with a message or baseband signal. It is used to:

- Facilitate transmission over long distances
- Improve signal robustness and immunity to noise
- Enable multiplexing of multiple signals
- Match the carrier signal's frequency with the transmission medium's frequency

2. Explain the concept of Amplitude Modulation (AM).

Answer: In amplitude modulation, the amplitude of the high-frequency carrier wave is varied in proportion to the message signal. The modulated wave contains the original message information in its envelope. The mathematical expression for an AM wave is:

$$s(t) = [A_c + m(t)] \cos(\omega_c t)$$

where:

- A_c = amplitude of carrier
- $m(t)$ = message signal
- ω_c = angular frequency of carrier

3. What are the advantages of AM?

Answer:

- Simplicity of transmitter and receiver design
- Ease of generation and demodulation
- Suitable for broadcasting over large areas

4. List the disadvantages of AM.

Answer:

- Susceptibility to noise and interference

- Inefficient power usage
- Large bandwidth requirement
- Low power efficiency

5. Define Frequency Modulation (FM). How does it differ from AM?

Answer: FM involves varying the frequency of the carrier wave in proportion to the message signal, while maintaining a constant amplitude. The instantaneous frequency of the carrier is shifted according to the message signal. Unlike AM, which encodes information in amplitude variations, FM encodes information in frequency variations, providing better noise immunity.

6. What is the bandwidth of an FM signal? State Carson's rule.

Answer: The bandwidth of an FM signal is given by Carson's rule:

$$BW = 2(\Delta f + f_m)$$

where:

- Δf = peak frequency deviation
- f_m = maximum frequency of message signal

This rule estimates the total bandwidth occupied by the FM signal, which is generally larger than the message bandwidth.

7. Describe the process of demodulation in AM and FM.

Answer:

- AM Demodulation: Uses a diode detector or envelope detector to extract the message signal from the modulated carrier.
- FM Demodulation: Uses frequency discriminators, phase-locked loops (PLLs), or ratio detectors to recover the original message signal from the frequency variations.

8. What is the significance of sidebands in AM?

Answer: Sidebands are the frequency components generated during modulation, located above and below the carrier frequency. They contain the actual information (message signal). The carrier itself does not contain data but facilitates the transmission of sidebands.

9. Explain the concept of Double Sideband Suppressed Carrier (DSB-SC) modulation.

Answer: DSB-SC involves modulating the carrier with the message signal but suppresses the carrier in the transmitted signal. The transmitted wave contains only the sidebands, which makes it more power-efficient. Demodulation requires a coherent detector that reintroduces the carrier.

10. What are the advantages and disadvantages of DSB-SC?

Answer:

- Advantages:
- Power efficiency due to the absence of carrier transmission
- Better utilization of power
- Disadvantages:
- Requires a coherent carrier for demodulation
- More complex receiver circuitry

Technical Concepts and Calculations

Understanding the technical aspects and being able to perform related calculations are often part of viva questions.

11. Derive the expression for the amplitude-modulated wave.

Answer: Starting from the message signal $m(t)$ and carrier $c(t) = A_c \cos(\omega_c t)$,

$$s(t) = [A_c + m(t)] \cos(\omega_c t)$$

$$\text{If } m(t) = A_m \cos(\omega_m t),$$

$$s(t) = A_c \cos(\omega_c t) + A_m \cos(\omega_m t) \cos(\omega_c t)$$

Using the product-to-sum formula:

$$s(t) = A_c \cos(\omega_c t) + \frac{A_m}{2} [\cos(\omega_c + \omega_m)t + \cos(\omega_c - \omega_m)t]$$

This shows the carrier and the two sidebands.

12. How is the modulation index defined in AM?

Answer: The modulation index, μ , is the ratio of the message signal amplitude to the carrier amplitude:

$$\mu = \frac{A_m}{A_c}$$

It indicates the extent of modulation; $\mu \leq 1$ for normal modulation.

13. Calculate the total power in an AM wave.

Answer: Total power is the sum of the carrier power and sideband power:

$$P_{\text{total}} = P_c \left(1 + \frac{\mu^2}{2} \right)$$

where $P_c = \frac{A_c^2}{2R}$, with R being load resistance.

14. How do you determine the bandwidth of an AM signal?

Answer: The bandwidth of an AM signal is twice the maximum frequency of the message signal:

$$BW = 2f_m$$

where f_m is the highest frequency component in the message.

15. What are the key differences between AM and FM?

Answer:

Aspect	AM	FM
Modulation parameter	Amplitude	Frequency
Bandwidth	Narrow	Wide
Noise immunity	Poor	Good
Power efficiency	Less	More

| Complexity | Simpler | More complex |

Practical and Conceptual Questions

Some viva questions focus on real-world applications and conceptual understanding.

16. Why is FM preferred over AM in high-fidelity broadcasting?

Answer: FM offers better noise immunity and higher fidelity because it is less affected by amplitude variations caused by interference. Its wider bandwidth allows for higher quality sound transmission, making it suitable for high-fidelity audio broadcasting.

17. What are the challenges faced in analog communication systems?

Answer:

- Noise and interference susceptibility
- Limited bandwidth efficiency
- Power inefficiency
- Signal distortion over long distances
- Difficulty in multiplexing large numbers of channels

18. How does a superheterodyne receiver work in analog communication?

Answer: The superheterodyne receiver converts the received radio frequency (RF) signal to a fixed intermediate frequency (IF) by mixing it with a locally generated oscillator signal. This simplifies filtering and amplification, improving selectivity and sensitivity.

19. Explain the importance of sideband suppression in communication systems.

Answer: Suppressing unwanted sidebands or the carrier reduces bandwidth usage and power consumption. Techniques like SSB modulation are used to improve efficiency, especially in satellite and amateur radio communications.

20. What are the applications of analog communication?

Answer:

- Radio broadcasting
- Television transmission
- Telephone communication
- Radar systems
- Audio and video transmission over wired and wireless channels

Demodulation involves extracting the message signal from the modulated carrier. In AM, this is typically done using an envelope detector, which rectifies the received signal and then passes it through a low-pass filter to recover the original message.

What are the common methods of demodulating FM signals?

Answer:

- Frequency Discriminator: Converts frequency variations into amplitude variations.
- PLL (Phase-Locked Loop): Tracks the frequency changes and regenerates the original message.
